

# A brief guide to T<sub>E</sub>X assistants\*

**Sebastian Rahtz**

ArchaeoInformatica  
York, England  
spqr@ftp.tex.ac.uk

This paper offers a ‘back to basics’ overview of the various types of software which are of assistance to the T<sub>E</sub>Xnical writer on a personal computer (this includes Unix machines, but excludes, for instance, VMS or VM/CMS systems). It is based on a presentation to the October UK-TUG meeting, and I am grateful to the other speakers, and our chairman Allan Reese, for insights and news. I would also like to refer readers to the Dutch T<sub>E</sub>X Group’s journal *MAPS*, whose issue 93.2 contains a variety of useful papers on T<sub>E</sub>X interfaces (two of which are reproduced in Baskerville Volume 3.2 (December 1993)).

Every T<sub>E</sub>X user knows that the traditional command-line way of working (the ‘edit ; compile; {preview, print}’ cycle) is far from ideal, and many people want some help. We may define eight different ways in which the environment we interact with can be improved:

1. Integrated environments (e.g. T<sub>E</sub>Xtures on Mac), where everything is tightly-coupled, and designed from the ground up to work together;
2. Integrating shells (e.g. T<sub>E</sub>Xshell), where a set of different programs are controlled by a single interface, which does its best to protect the user from their idiosyncrasies and errors;
3. Loosely-coupled packages (e.g. Windows, Desqview setups), where a multi-tasking environment is used to combine together various programs to provide a useful working environment;
4. T<sub>E</sub>X-aware editors (e.g. Gnuemacs AUCT<sub>E</sub>X package), which simplify the input of complex markup, and check syntax;
5. T<sub>E</sub>X super-scripts, including Makefile generators (e.g. ‘textit’); these take away the need to remember complicated program switches, and remembering which files are up to date, by understanding the rules about the different types of T<sub>E</sub>X-related files;
6. Super-previewers (e.g. xtex), which allow us to make greater use of the previewer to inspect and interact with our document.
7. Hypertext source convertors (e.g. latex2html), which make the tedium of writing generic markup with L<sup>A</sup>T<sub>E</sub>X more worthwhile by giving it a life beyond the printed page;
8. Friendly T<sub>E</sub>X programming; when we *do* interact with T<sub>E</sub>X’s enigmatic ‘\*’ prompt, we want macros to help

us, not hinder us. This is discussed by Jonathan Fine in Baskerville Volume 3.2 (December 1993).

Since most computer users seem to belong in distinct ‘camps’, based on machines and operating systems, it seems appropriate to examine what is on offer in each area.

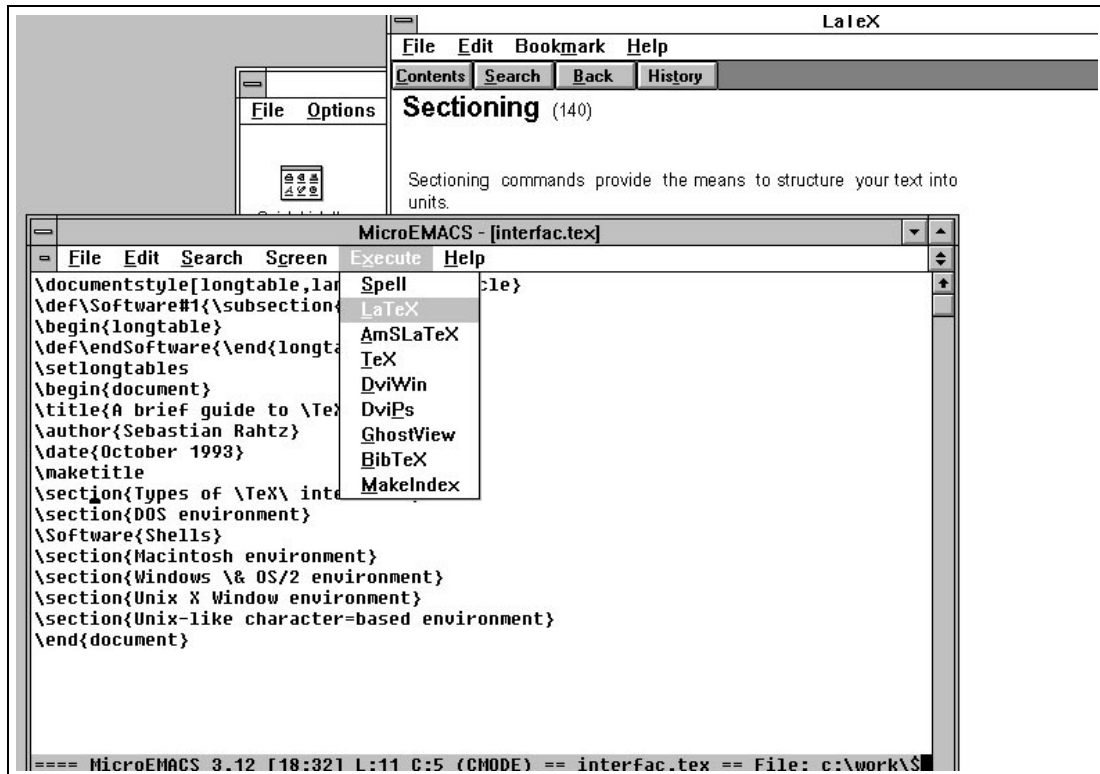

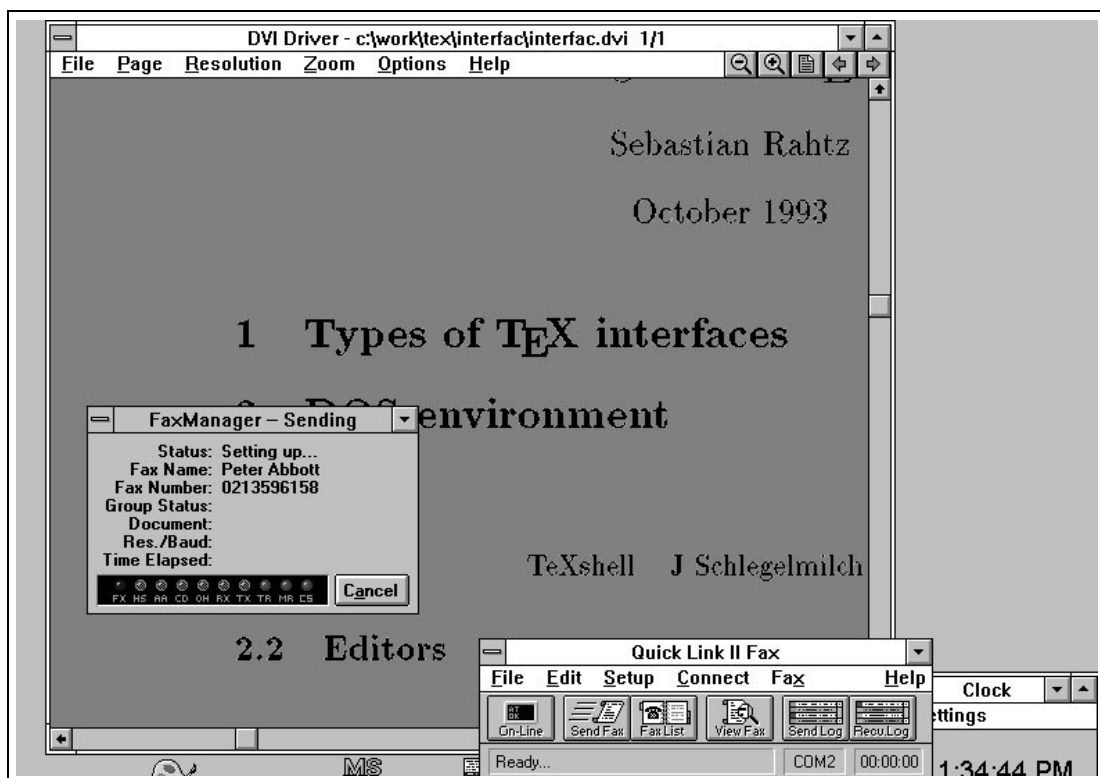

## 1 Windows, OS/2, and NT

For a fully-fledged Windows T<sub>E</sub>X, we have to look to the commercial companies: TurboT<sub>E</sub>X, from Kinch Computer Co, offers a full T<sub>E</sub>X, previewer, and drivers with a moderately-well integrated Windows interface, although (critically) it lacks a real integrated editor. The ‘traditional’ PC supplier of T<sub>E</sub>X, PCT<sub>E</sub>X, has also recently released a Windows setup, although it (like TurboT<sub>E</sub>X) fails to take advantage of builtin fonts properly. Y&Y sell a high-quality Windows previewer and PostScript driver, linked with a public domain T<sub>E</sub>X and commercial programmer’s editor, which work together well in a loosely-coupled way, and offer genuine integration with the Windows font systems (although the previewer has trouble using PK fonts). *Scientific Word* takes a different direction by offering a WYSIWYG writers interface (particularly for maths) which saves files in L<sup>A</sup>T<sub>E</sub>X format and does final formatting for printing with TurboT<sub>E</sub>X. None of these products, however, offer the same degree of integration and instant previewing as Textures on a Mac, and we still await the ‘real’ Windows T<sub>E</sub>X.

The more impoverished writer who wants to build her own Windows T<sub>E</sub>X setup has a not altogether easy time.<sup>1</sup> There is an excellent previewer, Hippocrates Sendoukas’ *Dviwin* (now at version 2.81, but *still* lacking support for virtual fonts, and nowhere near using the Windows system fonts), and the excellent emT<sub>E</sub>X ports of the basic T<sub>E</sub>X programs run in DOS windows (with some shenanigans necessary to change extended memory managers), but integration is left to the user. The powerful editor Microemacs has an adequate Windows port, extensible to allow T<sub>E</sub>X jobs (compiling, previewing, printing — see Figure 1) and context-sensitive help to be selected from menus, but it does not provide much protection for the user from the essentially unsatisfactory nature of Windows DOS boxes and multi-

\*Reprint from the Annals of the UK T<sub>E</sub>X Users’ Group: **Baskerville**, Volume 3.2, December 1993.

<sup>1</sup>Wietse Dol discusses this more fully in Baskerville Volume 3.2 (December 1993).

Figure 1: *Microemacs*  $\TeX$  menusFigure 2: *Dviwin* accessing Windows printer driver

tasking. The alternative, running a DOS  $\TeX$  shell in a DOS box under Windows, probably gives a better result (see Wietse Dol's article). But the convenience of access to Windows printer drivers (such as fax boards — see Fig-

ure 2) is a pointer to why this possibility should not be ignored.

Those converting to NT will, of course, have access to all the Windows tools, and the Unix ‘web2c’  $\TeX$  has been ported, but there do not yet appear to be any interfaces which make serious use of NT’s abilities.

OS/2 users are well served by the basic  $\text{em}\TeX$  kit, which has a proper Presentation Manager previewer, and by various shells (e.g.  $\text{PM}\TeX$ ) which make life easy. Given the good multi-tasking, Windows compatibility, and the availability of compilers to port most Unix tools (such as *Gnuemacs*, *make* etc), the OS/2  $\TeX$ ie has the best of almost all worlds.

## 2 DOS

The hard-pressed DOS user (or lover — there are a few) has a plethora of tools to make up for the inadequacies of the command line. The most mature of the ‘shell’ programs, which run  $\TeX$ , previewer, printer, editor etc for you sequentially when you select menu items from a character-based screen, is probably Jürgen Schlegelmilch’s  $\TeX$ shell (see Phons Bloemen’s article below). A typical screen is shown in Figure 3. Other offerings include Thomas Esken’s  $\TeX$ surface, Johannes Martin’s  $\TeX$ pert, Ulrich Jahnz’s  $\text{Eddi4}\TeX$ , the editors Redit and ET (see Reese’s article above) and Petr Olsak’s menu builder ‘mnu’. All of these have some or all of the following characteristics:

- a model of the original Turbo Pascal — character screens with pull-down menu bars;
- protection from the horrors of DOS environment variables controlling programs from four different authors (*after* you have got the shell properly configured);
- $\TeX$  and other programs activated by ‘shelling out’ to DOS, (an intrinsically ‘uncool’ procedure), with parsing of error messages;
- heavy use of customizable environments (see Figure 4), which can confuse the novice to screaming point;
- limited editors which can be difficult to use with ‘industrial strength’ documents;
- access to online  $\TeX$  context-sensitive help.

This is not to deny the great usefulness of parts of all of the DOS  $\TeX$  shells, but their parts are greater than their sum. The dedicated DOS  $\TeX$  user will find them extremely useful, but perhaps they can be summed up by saying that they will not convert many Microsoft Word users.

A recent initiative by Dutch  $\TeX$  users has resulted in  $\text{4}\TeX$  (see the article by Wietse Dol), a  $\TeX$  shell accompanied by a packaging of almost all the good public domain  $\TeX$  goodies. This is undoubtedly the system which is getting most support and development. The even more powerful  $\text{As}\TeX$  setup of Michel Lavaud (described in *TUGboat* 14.3, 238–44) unfortunately depends on commercial software for its implementation, but those interested in a wider perspective on *managing* their  $\TeX$  document library should examine this closely.

Those who want the approach of Scientific Word (WYSIWYG maths composition) in plain DOS can try the public

domain ET by John Collins, or the commercial *Leo* from ABK Software.

## 3 Macintosh systems

The Macintosh user does not need convincing about GUIs or integration; for hard cash, she can buy what is probably the fastest (given the processor), slickest  $\TeX$  around, Textures. A port of the Unix  $\TeX$  is available (C $\text{Mac}\TeX$ ), and a half-way house, the shareware  $\text{Oz}\TeX$ , which offers integration between a good compiler, previewer and printer driver, but not quite the smooth transition of Textures, or the use of system fonts. What is lacking on a Mac is a WYSIWYG interface to mathematical writing such as that offered by Scientific Word.

## 4 Unix, etc

The Unix  $\TeX$  user has a rich variety of tools to play with; like everything else in Unix, they are dangerously powerful, and require dedication to obtain true mastery. They start with simple things like the *cs*h or *ba*sh history mechanisms, which let you recall previous commands by name:

```
$ history
 171  lutex fine2
 172  dvips fine2
 175  latex interfac
 176  lpq
 180  dvips fine2 -o fine2.ps
 182  cp fine2.ps /user
$ !lat
$ !dv
```

Another universal Unix tool is ‘make’ which manages the relationship between different stages of a document’s ‘compilation’ from various sources, and keeps things up to date. A large book, with dozens of input files, hundreds of graphics inclusions from different programs, a bibliography managed with  $\text{Bib}\TeX$ , and an index, is likely to need such a tool to keep the author sane. There are various tools to help you write ‘make’ files, and to do similar jobs to ‘make’:

**imaketex** Just write an *imake* file and you just type ‘make’; as in ‘just write’...

**texit** A Perl script which makes educated guesses about the state of your  $\TeX$  file and helps you decide what to do next;

**latexmk** Given a  $\text{L}\TeX$  file this tries to work out what to do, like a ‘makefile’; but does not understand multiple-level dependencies;

**latex.make** A set of rules for real ‘make’, which understand a wide range of common  $\TeX$  jobs; but tailoring is not for the beginner. Sample ‘make’ rules are shown in Figure 5.

If you are already a Unix programmer, these are well worth investigating.

There do not appear to be any obvious public domain  $\TeX$  shells for the X Window system; the ‘doc’ editor does provide help in writing  $\text{L}\TeX$ , with limited immediate formatting, but it still leaves you to run  $\TeX$ . The Berkeley  $\text{Vor}\TeX$  program to produce an interactive  $\TeX$  ended some years ago without a real success (although various results

Figure 3:  $\TeX$ shell, after running  $\TeX$  and finding an errorFigure 4: Eddi4 $\TeX$  customization

have now been released for general use; they are available in CTAN).

The queen of Unix software is Gnuemacs; as well as being an *extremely* sophisticated editor, it provides hooks to run jobs synchronously or asynchronously from within the editor, and parse the output. The latest X Window version allows for user-defined menu bars, and multiple windows, which allows the Unix user access to as sophisticated a setup as almost everything except Textures. The actual editing can be enhanced with powerful Lisp routines to check syntax provide structure skeletons, edit in outline mode etc; the best-supported and enhanced package is Kresten Krab Thorup and Per Abrahamsen's AUCT $\TeX$ . If you can learn to be happy with Gnuemacs, this has al-

most limitless possibilities. An example screen is given in Figure 6.

## 5 Conclusions

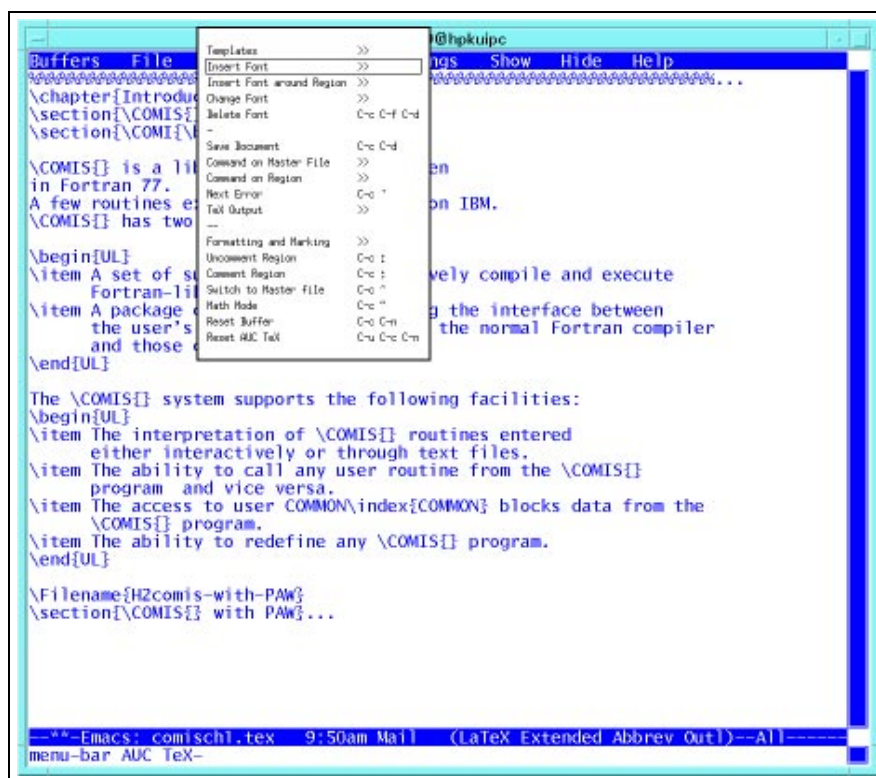

If you have to choose a  $\TeX$  environment, how do you start evaluating the offerings? I would suggest that base your choice on the following criteria:

- The editor; this is where you spend most of the time;
- On-line help;  $\LaTeX$  is unmemorable;
- Integration with windowing systems; doing just  $\TeX$  is dull;
- Lack of special features; compatibility with other  $\TeX$  setups is important;
- Integration with the 'style' of the environment (i.e. use of Adobe Type Manager).

```

# ensure that the bbl file gets regenerated if the bib file is changed
%.bbl : $(BIBFILES)
    @# if there is no aux file, skip this, it will get done later
    -@if [ -r $*.aux ] ;\
    then $(BIBTEX) $* ; \
    fi
# create a dvi file from a tex file
% %.dvi: %.tex
    $(LATEX) $*
    -@egrep -c 'Citation .* undefined.' $*.log && ($(BIBTEX) $*;$LATEX) $*)
    -@grep 'Rerun to get cross-references right' $*.log && $(LATEX) $*
# create postscript file of a dvi file
%.ps: %.dvi
    echo dvips -D $(PRINT_RES) -p $(PAGE_F) -l $(PAGE_T) -o $@ $*
    dvips -D $(PRINT_RES) -p $(PAGE_F) -l $(PAGE_T) -o $@ $*

```

Figure 5: An example of 'make' rules for a  $\TeX$  fileFigure 6: Gnuemacs and AUCT $\TeX$ 

For the five possible environments you might consider choosing:

- AUCT $\TeX$ : if you use the X Window system and *gnuemacs*, there is no other way to live;
- $\TeX$ shell: if you like plain DOS, this is well-designed and easily customized;
- Dviwindo: it really is a Windows application, and understands PostScript fonts;

- $\TeX$ tures: it works; it has semi-instant previewing; it integrates its fonts with the rest of the Mac;
- OS/2 and em $\TeX$ : a very good command-line  $\TeX$ , a Presentation Manager previewer, and integration with a reliable operating system.

[Note: all the public domain or shareware software referred to in this article can be found in the CTAN archives. The commercial vendors all advertise in TUGboat.]
